Introduction - Energy Recovery Ventilators

Fresh outside air must be supplied to indoor spaces to meet minimum mandated building code legislation (or greater volumes if required to improve occupant comfort) and provide make up air or positive room pressurisation where ever needed. However, providing fresh outside air to an indoor space comes with a significant energy penalty as any temperature differential between outside and inside increases the heating or cooling load required to condition this outside air to a space neutral temperature. The greater this differential, the greater the amount of energy required. Similarly, if the humidity present in the outside air exceeds that in the space it will need to be removed to maintain a space neutral condition. The removal of this excess humidity adds a latent component to the cooling load and further increases the energy required to maintain the desired room condition. The air conditioning necessary to provide outside air at a space neutral condition is known as the fresh air load ("FAL").

The most efficient way to remove this FAL is treat it separately to the normal sensible load that arises from the space use and the building fabric heat gain or loss by employing a dedicated outdoor air system ("DOAS"). An Energy Recovery Ventilator ("ERV") is a common form of DOAS which allows heat or energy to transfer between fresh outside air and air that is being exhausted in order to minimise the FAL.

Air Change have been manufacturing and supplying its DOAS ERV Range for over 20 years to a vast array of projects across Australia. By using its unique air-to-air heat and energy recovery technology, the Air Change ERV range is able to significantly reduce the running costs of HVAC systems needing fresh outside air. With a wide product range and design options available including integrated CHW and HHW coils, there is an Air Change ERV solution for any project.

Contact one of our experienced sales engineers for a detailed unit selection.

How it Works

Cooling Scenario

- 1. 100% fresh outside air enters the unit and passes through an air-to-air heat / energy exchanger where it exchanges heat (and moisture) with the return air (stage 3) that is to be exhausted.
- 2. Once the air has been precooled (or dehumidified) passing through the air-toair heat / energy exchanger, additional cooling is provided by an integrated CHW coil to maintain the desired room temperature. As an alternative to the the CHW coil, seperate equipment running in series or parallel to the ERV can provide the additional cooling.
- 3. Cool dry air returns to the unit where it exchanges heat / energy with the hot fresh air before it is exhausted from the building.
- 4. The now hot (and humid) return air from the space is exhausted outside.

Conversely, in a heating scenario the air-to-air heat exchanger provides preheating to minimise the outside air load. An integrated HHW coil (or seperate equipment) can provide additional heating when required.

2

The Advantages

The air-to-air heat / energy exchanger provides significant year-round energy savings by providing precooling in summer and preheating in winter.

Two heat / energy exchanger transfer media options are available: the sensible-only type which allows only temperature to be exchanged (suitable for temperate climates), and the enthalpy type which allows humidity to be exchanged alongside temperature (suitable for tropical climates).

Features

EC Supply Air and Exhaust Air Fans

EC fans offer optimal levels of energy efficiency. They also have high static pressure development, making them suitable for applications requiring high filtration grades or long ductwork runs. Budget friendly AC plug fans are available as an alternative option.

(Optional)

Dampers can be integrated into the unit to provide the optional operating modes of Economy Cycle and Return Air Bypass. See the schematics on the following page for details.

Air-to-Air Heat Exchangers

Air Change's unique counterflow plate heat / energy exchangers provide optimal heat transfer between outside air and return air, reducing the outside air load with significant running cost savings.

Additional Corrosion Resistance (Optional)

Unit components can be specially selected or surface treated for corrosion resistance to ensure reliable operation and longevity in harsh environments like pool halls or seaside buildings.

CHW and HHW Coils (Optional)

CHW and / or HHW coils can be integrated into the unit to provide room cooling and heating. The coils are sized and selected according to project specific requirements. Protective epoxy coatings are standard and ensure resistance to corrosion.

4

Operating Modes

100% Outside Air Heat Recovery (default)

Economy Cycle (optional)

Used for free-cooling - when cold 100% outside air is brought straight into an indoor space to address the room load. Also used when the outside air temperature is mild and air-to-air heat / energy recovery is not necessary for supplying 100% fresh outside air.

Used when 100% fresh outside

air is not required (eg. when room

occupancy levels are low). Outside air volume can be modulated between 0% and 100% to provide the minimum

required fresh air and achieve further

energy savings.

Used when the outside air temperature

is hot or cold, and the indoor space requires 100% fresh outside air. The

air-to-air heat / energy exchanger minimises the outside air load.

For more than 20 years, Air Change has provided unique equipment and engineering solutions for local and international clients using our internationally patented heat and energy recovery technology. During that time, we have developed a comprehensive range of energy efficient products to deliver controlled indoor climate conditions satisfying the requirements of all project stakeholders: the developer, the design engineer, and the building's owner and occupants.
